Authors' contributions

This work was carried out in collaboration among all authors. Authors AC, BNH and LW designed the study, performed the statistical analysis, wrote the protocol and wrote the first draft of the manuscript. Authors AC, SS and MCS managed the analyses of the study. Authors AC and AKA managed the literature searches. All authors read and approved the final manuscript.

ABSTRACT

The present investigations were carried out on forty genotypes of jackfruit (*Artocarpus heterophyllus* Lam.) to determine the extent of variability present in the material and association among different traits. The genotypes were collected from six north-eastern states of India *viz*. Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram and Tripura during the two years 2016 and 2017. Selection and identification of superior genotypes were done following IPGRI jackfruit descriptor. The experiment was laid using randomized block design with three replications during the year 2016 and 2017 under Department of Fruit Science, College of Horticulture and Forestry,

Central Agricultural University, Pasighat, East Siang, Arunachal Pradesh. The phenotypic coefficients of variability and genotypic coefficients of variability were recorded highest values for weight of fresh flake without seed (52.69% & 50.52%, respectively), stalk length (51.09% & 49.06%, respectively) and fruit weight (48.11% & 45.86%, respectively). High heritability coupled with high genetic gain was observed for stalk length, fruit weight, weight of fresh flake with seed and weight of fresh flake without seed traits. Genetic advance was recorded highest for 100-seed weight followed by stalk length and lowest for flake/fruit ratio followed by seed width traits. Yield per plant showed significant and positive genotypic correlation coefficient with fruit diameter, rachis diameter, fruit weight, petiole length, fruit length and flake length traits. The path coefficient analysis revealed that weight of fresh flake with seed has maximum positive direct effect on fruit yield per tree followed by weight of flakes per kg of fruit.

Keywords: Artocarpus heterophyllus; correlation; heritability; jackfruit; path analysis; variability.

1. INTRODUCTION

The jackfruit (*Artocarpus heterophyllus* Lam.) is a commercially important minor fruit crop of India. It is reported to be indigenous to the rainforest of the Western Ghats of India [1]. Barrau [2] suggests that Malaysia could be the centre of origin due to the presence of wide variability of cultivars but no wild trees have been observed there. Jackfruit is tetraploid with a somatic chromosome number of 56 (2n=4x=56). It belongs to the family Moraceae along with fig, mulberry and hedge apple [3,4]. The genus *Artocarpus* includes about 50 species with milky latex in the tropical Asia and Polynesia [2,5,6].

Jackfruit is cultivated throughout the tropical lowlands in south and south-east Asia, parts of central and eastern Africa and Brazil. Major jackfruit producers are Bangladesh, India, Myanmar, Thailand, Vietnam, China, the Philippines, Indonesia, Malaysia, Sri Lanka and Nepal. India is the second largest producer of the jackfruit and is widely distributed in the states of Assam, Tripura, Bihar, Uttar Pradesh, Kerala, Karnataka and Tamil Nadu [7]. In north-eastern India, the leading jackfruit producing states are Tripura, Meghalaya, Sikkim, Manipur and Assam [8]. The region comprising Assam and Tripura produces major share of jackfruit in India and the total annual production in Assam is estimated to be nearly 1,75,000 tonnes [7]. The area under jackfruit cultivation in homestead gardens of Tripura is approximately 2,200 hectares with the production of 12,500 MT [8].

Jackfruit tree is a multipurpose tree bearing largest edible fruit in the world and providing food, timber, fuel, fodder and medicinal products [9]. The tree is evergreen, medium-sized typically reaching 8-25 m in height producing fruits weighing upto 35 kg [10]. The fruit is a rich source of carbohydrates, proteins, vitamins,

minerals and dietary fibre. It possesses antiinflammatory, antioxidant, antifungal, immunomodulatory, anti-diabetic, anti-bacterial and antihelmintic properties [11]. The ripe fruit is eaten as raw and tender immature fruits can be used as vegetable. The fruits can be canned and processed into products like wine, ice-cream, chips, jellies [12], dehydrated bulbs and squash [13], vinegar [14], Preserve [15] and ready-toserve beverages [16].

There exists a lot of variability among jackfruit genotypes in north-eastern region since most are raised from seeds. The phenotypic and genotypic coefficients of variability are an important tool for estimating the amount of variations present in the investigated genotypes. The knowledge of linkage of yield with other yield contributing traits is a vital instrument as yield is not an independent character. This inter-relationship study is helpful in determining the components of yield but path coefficients analysis provides a clear picture of nature and extent of contribution made by number of traits.

Jackfruit is an important component of homestead garden in north-east India. But there is a lack of study on the diversity and variability of jackfruit in north-east India. Recently, there was a study carried out by Singh et al. [8] in Tripura. There is no study till date which has covered the entire north-eastern region. Therefore, the present investigation was taken to study the nature and extent of genetic variability and association of different horticultural traits with yield among the jackfruit genotypes found in the north-east India.

2. MATERIALS AND METHODS

The present investigation entitled "Appraisement of Variability and Association among the Jackfruit (*Artocarpus heterophyllus* Lam.) Genotypes

found in North-East India" was carried out on forty genotypes of jackfruit during the two years 2016 and 2017 under Department of Fruit Science, College of Horticulture and Forestry, Central Agricultural University, Pasighat, East Siang, Arunachal Pradesh. The selected genotypes were collected from six states of north-east India viz. Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram and Tripura (Table 1). Physical parameters were recorded on site and plant samples viz. leaves and fruit samples were collected for further physical and biochemical analysis. Selection and identification of superior genotypes were done following IPGRI jackfruit descriptor [17]. The experiment was laid in randomized block design with three replications. For fruit and leaf characters analysis, three fruits and twenty leaves are randomly selected from each replication for two consecutive years i.e. 2016 and 2017. The statistical analysis was carried out for each observed character by using MS-Excel, OPSTAT and SPAR 1.0 packages. The mean values of data were subjected to analysis of variance as described by Gomez and Gomez [18] for Randomized Complete Block Design.

The Genotypic and Phenotypic Coefficients of variability were calculated as per formulae given by Burton and De Vane [19].

a) Genotypic Coefficient of Variation (GCV)

GCV (%) =
$$\frac{\sqrt{\text{Genotypic variance (Vg)}}}{\text{General mean of population }(\bar{x})} \times 100$$

b) Phenotypic Coefficient of Variation (PCV)

PCV (%) =
$$\frac{\sqrt{\text{Phenotypic variance (Vp)}}}{\text{General mean of population }(\bar{x})}$$
 x 100

PCV and GCV values were categorized as low (0-10%), moderate (10-20%) and high (>20%) values as indicated by Sivasubranian and Menon [20].

Heritability in broad sense was calculated by the formula as suggested by Allard [21].

Heritability (%) =
$$\frac{Vg}{Vp}$$
 x 100

Where,

Vg = Genotypic variance [Vg = (Mg - Me) / r] Vp = Phenotypic variance [Vg + Ve] Heritability was classified as suggested Robinson et al. [22] into low (0-30%), moderate (30.1-60%) and high (>60%).

The expected genetic advance (GA) was worked out as suggested by Allard [21].

Genetic advance = H x 6 p x K

Where,

K = 2.06 (Selection differential at 5 per cent selection index)

6 р = Phenotypic standard deviation

H = Heritability in broad sense

Genetic gain expressed as per cent ratio of genetic advance and population mean was calculated by the method given by Johanson et al. [23].

Genetic gain (%) =
$$\frac{\text{Genetic advance}}{\text{General mean of population }(\overline{x})} \times 100$$

The GAM% was categorized into low (0–10%), moderate (10.1–20%) and high (>20%) as suggested by Johnson et al. [23].

The genotypic and phenotypic correlations were calculated as per Al-Jibouri et al. [24].

a) Genotypic correlation coefficient between X and Y

$$r_g = \frac{VgXY}{\sqrt{VgXxVgY}}$$

Where,

Vg XY = Genotypic covariance between X and Y Vg X = Genotypic variance of X

Vg Y = Genotypic variance of Y

Phenotypic correlation coefficient between X and Y

$$r_p = \frac{Vp XY}{\sqrt{Vp X \times Vp Y}}$$

Where.

Vp XY = Phenotypic covariance between X and Y

Vp X = Phenotypic variance of X

Vp Y = Phenotypic variance of Y

Genotypic variance (Vg) = (Mg - Me) / r Phenotypic variance (Vp) = (Vg + Ve)

The genotypic and phenotypic correlation coefficients were used in finding out their direct and indirect contribution towards yield per plant.

The direct and indirect paths were obtained by following Dewey and Lu [25]. The path coefficients were obtained by simultaneous selection of the following equations, which expresses the basic relationship between genotypic correlation 'r' and path coefficients (P).

$$r_{14}$$
: $P_{14} + P_{24} r_{12} + P_{34} r_{13}$
 r_{24} : $P_{14} r_{21} + P_{24} + P_{34} r_{23}$
 r_{34} : $P_{14} r_{31} + P_{24} r_{32} + P_{34}$

Where.

 r_{14} , r_{24} and r_{34} are genotypic correlations of component characters with yield (dependent variable) and r_{12} , r_{13} and r_{23} are the genotypic correlations among component characters (independent variables).

The direct effects were calculated by the following set of equations:

$$P_{14} = C_{11} r_{14} + C_{12} r_{24} + C_{13} r_{34}$$

$$P_{24} = C_{21} r_{14} + C_{22} r_{24} + C_{23} r_{34}$$

$$P_{34} = C_{31} r_{14} + C_{32} r_{24} + C_{33} r_{34}$$

Where, C_{11} , C_{22} , C_{23} and C_{33} are constants derived by using abbreviated Doulittle's technique as explained by Goulden [26].

$$\begin{matrix} r_{12} & P_{24}, & r_{13} & P_{34}, & r_{21} & P_{14}, & r_{23} & P_{34}, & r_{31} & P_{14}, & r_{32} & P_{24} \\ are indirect effects \end{matrix}$$

The variation in the dependent variable which remained undetermined by including all the variables was assumed to be due to variable (s) not included in the present investigation. The degree of determination of such variable (s) on dependent variable was calculated as follows:

1=
$$P^2x_4 + P_{14}^2 + P_{24}^2 + P_{34}^2 + 2P_{14} r_{12} P_{24} + 2P_{14} r_{13} P_{34} + 2P_{24} r_{23} P_{34}$$

3. RESULTS AND DISCUSSION

3.1 Variability Studies

The phenotypic and genotypic coefficients of variability are an important tool for estimating the amount of variations present in the available or investigated genotypes. Among all the studied traits, phenotypic coefficients of variability were higher in magnitude than genotypic coefficients of variability which indicate that these traits are influenced by environmental factors (Table 2). Coefficients of variability varied in magnitude from character to character which shows the presence of diversity in the evaluated genotypes. As jackfruit trees are cross-pollinated and mostly seed propagated, they showed high degree of

variability. The phenotypic coefficients of variability (PCV) were high for weight of fresh flake without seed (52.69%), stalk length (51.09%), fruit weight (48.11%), fruit yield per tree (44.76%), fruit rind weight (44.06%), weight of fresh flake with seed (41.22%), number of seeds/ kg of fruit (37.59%), number of flakes/kg fruit (36.18%), rachis diameter (32.96%), flake width (31.25%), reducing sugars (30.62%), 100seed weight (28.08%), petiole length (27.85%), stalk diameter (27.67%), flake/ fruit ratio (24.36%), weight of flakes/kg of fruit (24.32%), total sugars (24.23%), rachis length (23.75%), total carbohydrate of seed (20.88%) and TSS phenotypic (20.82%)whereas, moderate coefficients of variability (PCV) were recorded for flake length (19.03%), fruit length (18.72%), fruit diameter (17.25%), seed width (16.95%), leaf blade length (16.61%), leaf blade width (16.11%), protein content of seed (15.55%) and seed length (12.56%). The genotypic coefficients of variability (GCV) were recorded high for weight of fresh flake without seed (50.52%), stalk length (49.06%), fruit weight (45.86%), weight of fresh flake with seed (39.49%), fruit yield per tree (39.24%), fruit rind weight (38.93%), number of seeds/ kg of fruit (36.92%), number of flakes/kg fruit (35.62%), reducing sugars (29.04%), flake width (28.94%), rachis diameter (25.28%), stalk diameter (25.13%), 100-seed weight (22.94%), total sugars (22.77%), weight of flakes/kg of fruit (21.88%), flake/ fruit ratio (21.61%) and rachis length (20.56%) whereas, moderate genotypic coefficients of variability (GCV) were recorded for TSS (19.83%), petiole length (17.65%), total carbohydrate of seed (17.14%), fruit length (16.66%), flake length (16.45%), fruit diameter (16.25%), protein content of seed (13.68%), seed width (13.12%), leaf blade length (12.58%) and leaf blade width (11.28%)whereas, low GCV was recorded for seed length (9.47%) (Table 2).

These finding corroborate with the finding of Sharma et al. [27] and Maiti et al. [28]. Sharma et al. [27] observed high genotypic and phenotypic coefficient of variation for weight of bulbs without seed, weight of bulbs with seed and fruit weight. The phenotypic and genotypic coefficient of variation does not fully estimate the total heritable variations and therefore, computation of heritability becomes necessary. Burton and De-Vane [19] has suggested that genetic coefficient

of variability and heritability estimates would provide a reliable proof of expected amount of improvement through selection. The broad sense heritability estimates were found to be highest for the characters number of flakes/kg fruit (96.90%), number of seeds/ kg of fruit (96.50%), stalk length (92.20%), weight of fresh flake without seed (91.90%), weight of fresh flake with seed (91.80%), fruit weight (90.80%), TSS (90.80%), reducing sugars (89.90%), fruit diameter (88.70%),total sugars (88.30%), flake width (85.80%), stalk diameter (82.50%), weight of flakes/kg of fruit (80.80%), fruit length (79.20%), flake/fruit ratio (78.70%), fruit rind weight (78.10%), protein content of seed (77.40%), fruit yield per tree (76.90%), rachis length (74.90%), flake length (74.70%), total carbohydrate of seed (67.40%), 100-seed weight (66.70%) and seed width (60.00%) (Table 3).

The value of genetic advance ranged from 0.18 to 228.57. The highest genetic advance was recorded for 100-seed weight (228.57) followed by stalk length (203.09), protein content of seed (195.59), weight of flakes/kg of fruit (188.35), fruit

yield per tree (89.62) and total carbohydrate of seed (53.90). High heritability coupled with high genetic advance was observed for the traits weight of flake/kg of fruit, fruit yield per tree, 100seed weight, stalk length and protein content of seed indicating that these traits are highly heritable and likely to provide high selection response (Table 3). The genetic gain was found high for the characters viz. weight of fresh flake without seed (99.81%), stalk length (97.05%), fruit weight (90.04%), weight of fresh flake with seed (77.95%), number of seeds/ kg of fruit (74.70%), number of flakes/kg fruit (72.22%), fruit rind weight (70.87%), fruit yield per tree (70.87%), reducing sugars (56.74%), flake width (55.23%), stalk diameter (47.04%), total sugars (44.08%), weight of flakes/kg of fruit (50.57%), rachis diameter (39.95%), flake/ fruit ratio (39.51%), TSS (38.93%), 100-seed weight (38.59%), rachis length (36.65%), fruit diameter (31.53%), fruit length (30.55%), flake length (29.29%),total carbohydrate of seed (28.98%), protein content of seed (24.80%), petiole length (23.06%) and seed width (20.93%). Similar result was obtained by Wangchu et al. [29] and Maiti et al. [28].

3.2 Correlation Studies

Knowledge of degree of association of yield with its components is of great importance, because yield is not an independent character, but it is the resultant of the interactions of a number of component characters among themselves as well as with the environment in which the plants grow. Further, each character is likely to be modified by the action of genes present in the genotypes of plant and also by the environment and it becomes difficult to evaluate this complex character directly. Therefore, correlation study of yield with its component traits has been executed, to find out the yield contributing traits. The correlation coefficients among different characters were worked out at phenotypic and genotypic levels. The phenotypic correlation coefficients among different characters revealed that fruit yield per tree had positive and significant correlation with fruit diameter (0.526), fruit weight (0.454), rachis diameter (0.433), fruit length (0.378), rachis length (0.355), fruit rind weight (0.325), flake length (0.319), reducing sugars (0.262), stalk length (0.255), seed length (0.255), petiole length (0.248), total sugar (0.244) and 100-seed weight (0.213) (Table 4). Similar results were obtained by Maiti [30] who recorded significant association of yield with fruit weight and fruit rind weight. These results are also in line with the work of Sharma et al. [31] indicating the scope of effective selection from these characters. Fruit weight was significantly positively correlated with fruit diameter followed by fruit length and fruit rind weight. Similar results was obtained by Wangchu et al. [29] who observed high significant positive association of rind weight, rachis length, fruit length and flake length with fruit weight. The genotypic correlation coefficients of different characters showed that fruit yield per tree had significant and positive correlation with fruit diameter (0.556), rachis diameter (0.523), fruit weight (0.466), petiole length (0.430), fruit length (0.389), flake length (0.381), leaf blade width (0.359), rachis length (0.358), seed length (0.326), reducing sugar (0.318), fruit rind weight (0.310), total sugar (0.299), 100-seed weight (0.287), stalk length (0.284), leaf blade length (0.208) and weight of flakes per kg of fruit (0.202) (Table 5). Similar correlations of yield with various horticultural traits had also been reported by Sharma and Sharma [32] in strawberry, who observed that yield per plant was significantly and positively associated with fruit length and fruit breadth. In the present study, the genotypic correlation coefficients were higher in magnitude than phenotypic correlation coefficients for most of the traits, this means that there is a strong association between any two characters, but the phenotypic values are lessened by the significant interaction of environment. Sharma et al. [31] also found higher genotypic correlation than phenotypic correlation coefficients coefficients for most of the characters. The characters such as number of flakes per kg of fruit, weight of fresh flake with seed, weight of fresh flake without seed, flake/fruit ratio, flake width, seed width, number of seeds per kg of fruit and total soluble solids showed no significant association with yield revealed that yield was independent of these characters. These findings is not in accordance with the finding of Maiti [30] who observed significant correlation of fruit weight with number of seeds and number of flakes.

3.3 Path Analysis

Although correlation studies are helpful in determining the components of yield but it does not provide a clear picture of nature and extent of contributions made by number of independent traits. Path coefficient analysis devised by Dewey and Lu [25], provides a realistic basis for allocation of appropriate weightage to various attributes while designing pragmatic а programme for the improvement of yield. The path coefficient analysis at phenotypic level revealed that weight of fresh flake without seed (21.1008) has maximum positive direct effect on fruit yield per tree followed by 100-seed weight (5.6297), number of seeds per kg of fruit (1.7891), weight of flakes per kg of fruit (0.6414), rachis length (0.5074), fruit diameter (0.3871), flake length (0.3136), reducing sugar (0.2413), leaf blade width (0.1527), total carbohydrate content of seed (0.1512), rachis diameter (0.1393), protein content of seed (0.1220), TSS (0.0992), fruit weight (0.0835), seed width (0.0769), petiole length (0.0753), stalk length (0.0700) and seed length (0.0345) (Table 6). In accordance with present investigation, Wangchu et al. [29] also observed positive direct effect of stalk length, fruit weight, weight of flakes per kg of fruit, flake length and 100-seed weight on fruit yield per tree. Further, the negative direct effect of weight of flake with seed, flake/fruit ratio, number of flakes per kg of fruit, fruit length, leaf blade length, stalk diameter, fruit rind weight, total sugar and flake width was observed on fruit vield per tree. Under this situation indirect selection for such traits should be practiced to reduce the undesirable direct effect. At genotypic level, weight of fresh flakes with seed (96.5952) has maximum positive direct effect on fruit yield

per tree followed by weight of flakes per kg of fruit (9.7365), number of seeds per kg of fruit (6.5417), fruit length (4.3799), protein content of seed (1.6243), rachis diameter (1.6010), flake length (1.4732), reducing sugar (1.3496), leaf blade width (1.0691), seed width (0.9405), TSS (0.8564), fruit rind weight (0.6448), total sugar (0.3028), leaf blade width (0.1082) and fruit weight (0.0638). While, negative direct effect of weight of fresh flake without seed, 100-seed weight, flake/fruit ratio, rachis length, number of flakes per kg of fruit, fruit diameter, flake width, petiole length, stalk diameter, seed length, stalk length and total carbohydrate content of seed was observed on fruit yield per tree (Table 7). These findings will help in selecting superior genotypes. This is in accordance with some of the findings of Wangchu et al. [29] who recorded direct effect of fruit length, fruit weight, flake length and number of seed per kg of fruit on fruit vield.

4. CONCLUSION

The phenotypic coefficients of variability and genotypic coefficients of variability were recorded high for weight of fresh flake without seed, stalk length and fruit weight whereas low for seed length, leaf blade width and leaf blade length, respectively. High heritability coupled with high genetic gain was observed for stalk length, fruit weight, weight of fresh flake with seed and weight of fresh flake without seed. Genetic advance was recorded highest for 100-seed weight followed by stalk length and lowest for flake/fruit ratio followed by seed width. The correlation coefficients among the different characters were worked out at both phenotypic and genotypic levels. Genotypic correlations in general, were higher in magnitude than phenotypic ones. Yield per plant showed significant and positive genotypic correlation coefficient with fruit diameter, rachis diameter. fruit weight, petiole length, fruit length, flake length, leaf blade width, rachis length, seed length, reducing sugar, fruit rind weight, total sugar, 100-seed weight, stalk length, leaf blade length and weight of flakes per kg of fruit. At phenotypic level, yield per plant was positively and significantly associated with fruit diameter, fruit weight, rachis diameter, fruit length, rachis length, fruit rind weight, flake length, reducing sugars, stalk length, seed length, petiole length, total sugar and 100-seed weight. The path coefficient analysis revealed that weight of fresh flake with seed has maximum positive direct effect on fruit yield per tree followed by weight of flakes per kg of fruit, number of seeds per kg of

fruit, fruit length, protein content of seed, rachis diameter, flake length, reducing sugar and leaf blade width on fruit yield at genotypic level. At phenotypic level, weight of fresh flake without seed has maximum positive direct effect on fruit yield per tree followed by 100-seed weight and number of seeds per kg of fruit. From this it is clear that there is a true relationship of these characters with yield and direct selection for this trait will be rewarding for the yield improvement in jackfruit.

ACKNOWLEDGEMENT

The author is thankful to the Department of Fruit Science and Department of Basic Sciences and Humanities, College of Horticulture and Forestry, Central Agricultural University, Pasighat for providing fund and support for conducting this research.
